DID YOU KNOW?

Phosphorus was first discovered in urine. German chemist Hennig Brand was examining urine as a substance that might help him turn other metals into gold.

Another important use of urinalysis is for pregnancy testing. When a woman becomes pregnant, a hormone known as human chorionic gonadotropin begins to be secreted by the embryonic tissues shortly after fertilization. HCG secretion then increases until it reaches a peak in about fifty to sixty days; thereafter, the HCG concentration drops to a much lower level and remains relatively stable throughout the pregnancy. Because HCG is excreted in the urine, urinalysis is used to detect this hormone, thereby indicating the presence of an embryo. Such a pregnancy test may give positive results as early as eight to ten days after fertilization.

Several factors are examined when analyzing a urine sample. These include appearance of the urine, odor, pH, specific gravity, and microscopic observations.

Appearance

The color of normal urine can range from pale yellow to amber, depending on the concentration of the pigment urochrome, which is the end product of hemoglobin breakdown. The appearance of the urine may serve as an indication of a pathological condition. For instance, pale yellow urine may indicate diabetes insipidus, granular kidney, or may simply be very dilute due to ingestion of copious amounts of water. A milky color might signify fat globules or pus corpuscles, the latter possibly indicating a urogenital tract infection. Reddish colors may be due to food pigments (such as beets), certain drugs, or blood in the urine. Greenish colors indicate either bile pigment (jaundice) or certain bacterial infections, such as those caused by several species of *Pseudomonas*. Lastly, brown-black urine can indicate phenol or metallic poisonings or hemorrhages due to conditions such as renal injury or malaria.

Odor

The odor of urine can vary greatly according to both diet and pathology. An ammonia smell may result from certain foods, while a fishy smell may indicate cystitis. A fecal smell could be due to an intestinal-urinary tract fistula. Other distinctive smells could be indicative of disorders such as acetonuria, which has an overripe apple smell, or diabetes, the urine of which can also be noted to be sweet-smelling.

pH

The pH of normal urine ranges from 4.5 to 8.0, the acidity or alkalinity of which can fluctuate depending on the type of food ingested. Pathological conditions can also affect the pH of urine. Fevers and acidosis lower the pH, whereas anemia, vomiting, and ischuria (urine retention) raise the pH.
